

本节主题:

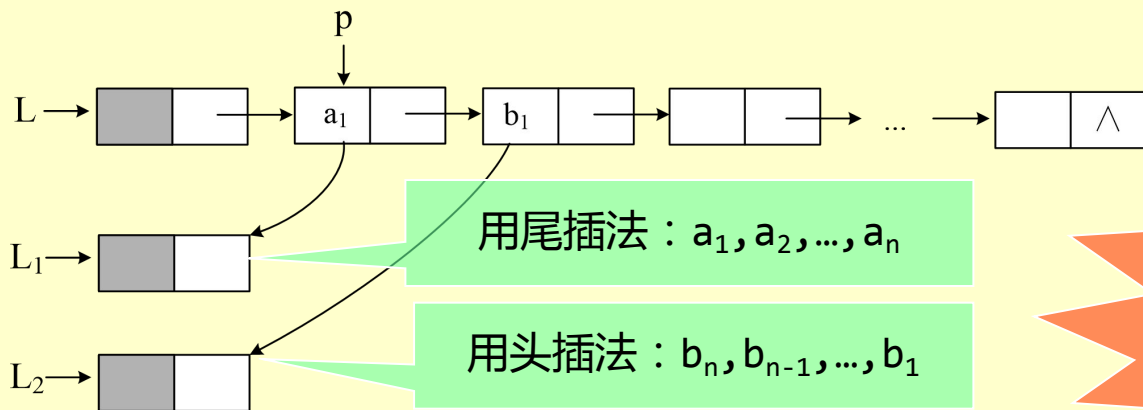

单链表应用举例

# 例：拆分单链表

## 问题

- 有一个带头节点的单链表  $L = \{a_1, b_1, a_2, b_2, \dots, a_n, b_n\}$
- 设计一个算法将其拆分成两个带头节点的单链表  $L_1$  和  $L_2$  :
- $L_1 = \{a_1, a_2, \dots, a_n\}$  ,  $L_2 = \{b_n, b_{n-1}, \dots, b_1\}$
- 要求  $L_1$  使用  $L$  的头节点

## 分析

**L1直接使用L的空间即可！**

```
void split(LinkList *&L, LinkList *&L1, LinkList *&L2)
```

```
{
```

```
    LinkList *p=L->next,*q,*r1;
```

```
    L1=L;
```

```
    r1=L1;
```

```
    L2=(LinkList *)malloc(sizeof(LinkList));
```

```
    L2->next=NULL;
```

```
    while (p!=NULL)
```

```
    {
```

```
        r1->next=p;
```

```
        r1=p;
```

```
        p=p->next;
```

```
        q=p->next;
```

```
        p->next=L2->next;
```

```
        L2->next=p;
```

```
        p=q;
```

```
    }
```

```
    r1->next=NULL;
```

```
}
```

## 例：删除元素最大的节点

设计一个算法，删除一个单链表L中元素值最大的节点。

# 删除元素最大的节点

```
void delmaxnode(LinkList *&L)
```

```
{
```

```
    LinkList *p=L->next,*pre=L,*maxp=p,*maxpre=pre;
```

```
    while (p!=NULL)
```

```
    {
```

```
        if (maxp->data < p->data)
```

```
        {
```

```
            maxp=p;
```

```
            maxpre=pre;
```

```
        }
```

```
        pre=p;
```

```
        p=p->next;
```

```
    }
```

```
    maxpre->next=maxp->next;
```

```
    free(maxp);
```

```
}
```

## 例：增序排列节点

问题：有一个带头节点的单链表L（至少有一个数据节点），设计一个算法使其元素递增有序排列。

```
void sort(LinkList *&L)
```

```
{
```

```
    LinkList *p,*pre,*q;
```

```
    p=L->next->next;
```

```
    L->next->next=NULL;
```

```
    while (p!=NULL)
```

```
    {
```

```
        q=p->next;
```

```
        pre=L;
```

```
        while (pre->next!=NULL && pre->next->data<p->data)
```

```
            pre=pre->next;
```

```
        p->next=pre->next;
```

```
        pre->next=p;
```

```
        p=q;
```

```
    }
```

```
}
```
